

INTELLIGENT WORKFORCE ORCHESTRATION

CHIMAERA

A plain-language guide to turning project needs into the right human collaboration.

PROJECT OVERVIEW / WORKING PROTOTYPE

00 / PROJECT BRIEF

CHIMAERA at a glance

CHIMAERA helps a small team answer a simple but difficult question: who is the right person to help with this work?

Different minds. One creation.

- A user describes a project or collaboration need in ordinary language.
- The system turns that description into a clear set of skills.
- Eligible people are ranked using their saved profile information rather than a hardcoded list.
- The requester sees the top three choices and decides who should receive an invitation.
- The selected person can review, accept, decline or remove the invitation.
- An accepted invitation opens a private conversation between the two people.

In one sentence

CHIMAERA is a people-first coordination assistant that combines skill discovery, explainable recommendations and human approval in one workflow.

01 / PROJECT BRIEF

The problem statement

- Small teams often know that help is available, but they do not have a reliable, current view of who knows what.
- Project requests usually arrive as informal messages. Someone still has to interpret the need, identify the skills and search for the right person.
- Selection frequently depends on personal memory, visibility or seniority instead of evidence from the whole team.
- A capable employee may be overlooked, while the same visible person receives too many requests.
- Profiles, resumes, project requests and conversations are commonly spread across separate tools.
- When an automated recommendation is unexplained or sends a request without permission, people are less likely to trust it.

Core question

How can a small team translate an informal project need into a fair, useful and consent-based collaboration decision?

Who is affected?

- Team members looking for help.
- Employees whose skills are not easily visible.
- Team leads trying to distribute work responsibly.
- Small organizations that cannot maintain a large specialist staffing operation.

02 / PROJECT BRIEF

The gap in existing products

Many products solve one part of the problem. The gap appears between those parts.

Product category	Usually does well	Common gap for small-team orchestration
Project management	Tracks tasks, deadlines and progress.	Usually begins after a person has already been chosen.
Hiring and applicant systems	Searches external candidates and manages recruitment.	Not designed for quick internal collaboration between existing members.
Resource planning	Shows schedules and utilization.	Often requires managers to translate needs and skills manually.
Generic AI assistants	Drafts plans and summarizes text.	May not connect identity, profiles, permissions, requests and follow-up actions.

The opportunity

Join understanding, recommendation, consent and communication in one simple path without pretending that software should make the final human decision.

03 / PROJECT BRIEF

The solution

- Convert natural-language project descriptions into editable skill requirements.
- Search live member profiles and exclude people who are unavailable, private or otherwise ineligible.
- Rank suitable collaborators and show the strongest three choices instead of forcing only one answer.
- Display an understandable match score and the skills that support the recommendation.
- Require the requester to choose a person and explicitly approve the invitation before it is sent.
- Give the recipient control to review, accept, decline or remove the request.
- Open a private chat only after both sides have agreed to collaborate.

04 / PROJECT BRIEF

Our approach

- Human-controlled: AI recommends; people decide.
- Live, not hardcoded: recommendations come from saved profiles and current eligibility.
- Explainable: the current model uses transparent skill similarity rather than presenting a mysterious success probability.
- Privacy-aware: identity, profile access and resume access are checked by the backend.
- Modular: the interface, business rules, AI service, identity provider and database are separate components.
- Prototype-first: each important workflow is tested before more advanced machine learning is added.

05 / PROJECT BRIEF

An introduction to CHIMAERA

CHIMAERA is an intelligent workforce orchestration platform created for small teams. It is designed to make collaboration discovery feel as natural as asking a colleague for help, while keeping the process structured, secure and reviewable.

INPUT	INTELLIGENCE	DECISION	COLLABORATION
A project need written in everyday language.	Skill extraction and live candidate ranking.	A person selects and approves one of the top three.	Invitation, response and private chat.

What CHIMAERA is not

- It is not an autonomous manager that assigns people without consent.
- It is not a claim that a match score predicts human success.
- It is not yet a finished enterprise product; it is a tested working prototype with a clear production roadmap.

Design principle

The strongest system is not the one that removes people from the decision. It is the one that gives people better evidence and a safer way to act.

06 / PROJECT BRIEF

Features of CHIMAERA

Natural-language agent Reads a project request and proposes a practical skill profile.	Top-three recommendations Lets the requester compare and choose, instead of contacting only the highest score.
Profile and skill management Members can maintain their organization, skills, experience and availability.	Resume parsing Extracts useful profile information from text-based resumes and keeps the result editable.
Secure authentication Uses Supabase sessions while the backend verifies identity before protected actions.	Invitation inbox Recipients can review, accept, decline or remove collaboration requests.
Sent-request tracking Requesters can see the invitations they have already sent and their status.	Private chat Becomes available only after an invitation is accepted.
Protected resumes Resume access is limited to authorized workflow participants.	Light and dark themes Provides white-and-gold and black-and-crimson visual modes.
Bounded concurrency Prevents unlimited AI work from overwhelming the service.	FAQ and edge cases Explains unusual outcomes, privacy rules and service-failure behavior.

07 / PROJECT BRIEF

The architecture

CHIMAERA is built as connected services. Each part has one clear responsibility, which makes the system easier to test, replace and scale.

- React and Vite: the website people use for profiles, requests, recommendations, inbox decisions and chat.
- Spring Boot: the trusted control layer that applies permissions and workflow rules.
- FastAPI AI service: extracts requirements and ranks candidates using transparent skill relevance.
- MySQL: the system of record for profiles, normalized skills, requests, proposals, resumes and messages.
- Supabase Authentication: manages registration, sign-in and secure user sessions.
- Flyway migrations: updates the database in controlled, versioned steps.

08 / PROJECT BRIEF

Results obtained

16 / 16	11 / 11	200
backend tests passing	AI tests passing	live service health

- The frontend produces a successful optimized build.
- The backend, AI service, frontend and database run together as a working local prototype.
- Protected endpoints reject anonymous access, and invalid tokens return an authorization response rather than crashing the server.
- The implemented model detects real profile skills, excludes ineligible members and does not depend on fixed candidate identities.
- The interface works in both themes and at desktop and mobile widths without horizontal overflow.
- The authenticated workspace, profile synchronization and Supabase token verification have been checked in the running product.

How this approach is different

- It connects the full path from informal need to approved collaboration, rather than stopping at planning or search.
- It offers the top three candidates and preserves user choice instead of allowing a model to contact only the top score.
- It combines consent, privacy checks, resume access and post-acceptance chat in the same workflow.
- Its current scores are described honestly as skill similarity, not guaranteed performance predictions.
- It is designed for the speed and simplicity required by small teams.

Important qualification

CHIMAERA has useful prototype differentiation, but a controlled benchmark against commercial products and real collaboration outcomes is still required before claiming market-wide superiority.

09 / PROJECT BRIEF

Future integrations

Smarter matching	- Semantic skill understanding - Learning from accepted and successful work - Bias and fairness monitoring
Work planning	- Calendar and leave integration - Live workload and capacity - Team construction and task allocation
Organization controls	- Separate company workspaces - Manager and administrator roles - Department-level skill maps
Communication	- Email, Slack or Teams notifications - Calendar invitations - Mobile and push notifications
Resume safety	- Private object storage - Malware scanning - Retention and consent controls
Production operations	- Cloud deployment and HTTPS - Central logs, metrics and alerts - Backups, load tests and disaster recovery

The direction

Grow from a strong collaboration prototype into a trusted workforce intelligence layer without losing transparency, consent or human control.
